

DESCRIPTION OF *RETUSA CHRYSOMA* BURN SP. NOV.  
(OPISTHOBRANCHIA) AND ITS FOOD RESOURCES FROM  
CORNER INLET, VICTORIA

By ROBERT BURN and K. N. BELL

Honorary Associates, National Museum of Victoria, Melbourne

Abstract

*Retusa chrysoma* Burn sp. nov. is described from Corner Inlet, Victoria, and compared with other species reported from the Victorian coastline. Gizzard contents show selective food preferences for foraminifera and juveniles of the air breathing gastropod *Salinator fragilis* (Lamarck, 1822).

Introduction

Little is known anatomically of the shell-bearing opisthobranch molluscs of Victoria. Similarly, little is known of their food resources and selective preferences. Foraminifera are believed to form wholly or part of the food of several species of retusid opisthobranchs (Bacescu and Caraion 1956, Marcus and Marcus 1969, Moore 1961, Morton 1958, Rudman 1971), but the overall part they play in the marine food-energy cycle is poorly known (Lipps and Valentine 1970).

In order to study Australian species/food resources, we have examined a new species of *Retusa* collected by one of us (K.N.B.) at Corner Inlet, Victoria. The description of *Retusa chrysoma* has been prepared by the first author (R.B.), the analysis of the food resources by the second author (K.N.B.).

The type series of *Retusa chrysoma* and a series of foraminiferans from the gizzard contents, mounted on slides, have been presented to the National Museum of Victoria, Melbourne. The first author (R.B.) expresses his gratitude to the Science and Industry Endowment Fund, C.S.I.R.O., for continued support of this and other research on Australian opisthobranch molluscs.

Systematic Description

Order CEPHALASPIDEA

Superfamily BULLACEA

Family RETUSIDAE

*Retusa chrysoma* Burn sp. nov.

Figures 1-3

*Description.* Shell (Fig. 1) small, cylindrical,

rounded anteriorly, obliquely truncate posteriorly. Colour pale yellow, thin periostracum golden yellow. Sculpture, faint growth lines at anterior end develop into raised riblets on posterior third, riblets passing obliquely over shoulder into vertex; encircled by fine, variably spaced, wavy lines, less noticeable posteriorly where the riblets are strongest. Aperture anteriorly pyriform, medially narrow and slightly constricted, posteriorly rising above the last whorl and inclined towards the axis. Columella thickened, with a nearly vertical plait rising at mid-length, with a broad reflexion behind the plait. Spire deeply sunk, shoulder of the preceding whorl visible, sculptured by oblique riblets descending to a large, smooth, papillary protoconch. Dimensions (length x breadth): Holotype 3.06 x 1.425 mm, largest paratype 3.0 x 1.5 mm, smallest paratype 1.425 x 0.78 mm, figured specimen (dry shell) 2.7 x 1.3 mm.

Animal cream; head quadrate, broader than long, with a pair of broad, thin lobes posteriorly; yellowish Hancock's organs in furrow between head and foot and close to mouth, strongly developed, thickened, harder than the surrounding skin, each with 3 or 4 shallow transverse folds; foot short, rounded anteriorly, truncate posteriorly. Gastral plates (Fig. 2) with many dark tubercles of various sizes, tubercles largest and highest posteriorly; largest plate convex on inner face, smaller plates concave. Male copulatory organ (Fig. 3) on right side of oesophagus; atrium long, dilated entally with folded walls, ciliated seminal groove to opening of elongate seminal

Figs. 1-3—*Retusa chrysoma* Burn sp. nov.

1, Shell. 2, Gastral plates. 3, Male copulatory organ. (Figs. 2-3 drawn to same scale).

vesicle, retractor muscle attached to end of vesicle; prostate gland shorter than vesicle, filled with shining cells, narrower near atrium and with short papilla in penial sheath.

**Material examined.** From *Zostera* and mud flats on N. side of Rocky Point reef, at E. end of Bluff Road, Yanakie, Corner Inlet, Viet., collected by K. N. Bell, 11 April 1971, seven specimens (NMV F27490); 1 April 1972, eight specimens (Holotype NMV F27488 and seven paratypes NMV F27489). The specimens were obtained by sieving the top 1 cm of the substrate at mid-tide level. Other opisthobranchs inhabiting the same biotope were *Tornatina* cf. *apicina* (Gould, 1859) and *Cylichnatys* sp. nov. (Scaphandridae), and *Liloa brevis* (Quoy and Gaimard, 1833) (Atyidae).

**Etymology.** *Chrysoma* Gk. = a gold object,

vessel, plate, dress; in reference to the colour of the shell.

**Discussion.** The authors wholeheartedly agree with Valentine's comment (1965, p. 42) that "The forms of *Cylichnina* (i.e. *Retusa*) living in SE. Australia merit review." Examination of large series of dry shells from different localities lead us to believe that little can be achieved by this method, yet, hitherto, all Australian records of retusids and other shelled opisthobranchs have been based upon dead shells. The small amount of material collected alive that we have so far examined suggests that the animal has much importance for separating one species from the next, and that there are many local species.

In dealing with retusids of SE. Australia, we follow Rudman (1971, p. 192) in allocating those species with tubercles on the gastral

plates to *Retusa* Brown, 1827, and those with smooth gastral plates to *Relichna* Rudman, 1971. The type species of *Cylichnina* Monterosato, 1884, *umbilicata* (Montagu, 1804), has tuberculate gastral plates (Pilsbry, 1893, p. 204, pl. 60, fig. 8) and is no longer held separate from *Retusa* (Lemche, 1948, p. 50). *Cylichnina* must therefore be expunged from Australian faunal lists and replaced by *Retusa*.

There are only four species of *Retusa* reported from the Victorian coastline (Macpherson and Gabriel 1962, p. 243). *R. amphizosta* (Watson, 1886) was recorded from Portsea by Gatliff and Gabriel (1908, p. 384). Hedley (1914, p. 753) suggested their specimens might be his *R. iredaleana* (1914, p. 752). After study of a British Museum (Natural History) photograph of one of the three syntypes of *Bulla* (*Cylichna*) *pygmaea* A. Adams, 1854, from Port Lincoln, S. Aust., we are inclined to think that *R. iredaleana* from Middle Harbour, Sydney Harbour, N.S.W., and Gatliff and Gabriel's specimens are referable to *R. pygmaea*. *Cylichnina atkinsoni* (Tenison Woods, 1875) has tuberculate gastral plates (personal observations) and must be transferred to *Retusa*. The *C. pygmaea* of Macpherson and Gabriel (1962, p. 243) may refer to another, apparently new, species of *Retusa* that we have from Port Phillip Bay and Shallow Inlet, Vict. It differs from true *R. pygmaea* in the narrower shape of the shell and greater inclination of the posterior lip of the aperture. *R. sculpta* (Gatliff and Gabriel, 1913) has both spiral and axial sculpture, and may be a juvenile form.

The new species, *R. chrysoma*, is distinguished from each of the above species by the riblets of the posterior third of the shell and the fine wavy spiral lines on the remainder of the surface. From species for which the animal is known, *R. chrysoma* differs in the density of the tubercles on the gastral plates.

### Gizzard Contents

Live specimens of *Retusa chrysoma* Burn were collected and preserved in 70% alcohol for later study. After carefully fracturing each

shell, the gizzard was dissected out, and the contents removed.

To see if any selection for food had occurred a sample of the sediment of the biotope was collected and placed in 70% alcohol. This sample was later washed to remove any preservative, placed in rose Bengal stain (1 g/l solution) for one hour, washed and dried. Foraminifera were concentrated by flotation in carbon tetrachloride. The rose Bengal stains the protoplasm of living specimens a deep red (Walton 1952).

### Results

The gizzard contents of 11 specimens of *R. chrysoma* consisted of 43 specimens of foraminifera belonging to six species (Table 1) and nine specimens of juveniles of *Salinator fragilis* (Lamarck, 1822). Also present were 17 chitinous opercula which appear to be identical with the operculum of *S. fragilis*. Table 2 shows the contents of each specimen of *R. chrysoma*. From the sediment sample 15 species of living foraminifera were recovered (Table 3).

Although the number of specimens studied is small, there is evidence for selection in their food intake. This is most clearly seen with *Quinqueloculina seminula* which constitutes only 7.5% of the foraminiferal fauna but 28% of the foraminiferal food intake. The higher percentages of the food intake of *Elphidium simplex*, *E. advenum depressulum* and *Ammonia aoteanus* may not be significant considering the small numbers involved. The lack of any specimens of *Q. seminula jugosa* as food shows a definite selection against this species. The lack of other foraminiferal

TABLE 1

Foraminifera in the gizzard of *R. chrysoma*

species is most likely due to their normal infrequency in the sediment.

More evidence of food selection is shown by the presence of *Salinator fragilis*. Nine specimens and 17 separate opercula were found indicating that this gastropod forms a major food source of *R. chrysoma*.

None of the specimens, foraminiferan or molluscan, showed any evidence of crushing from the gastral plates. This is in agreement with the observation of Mareus and Marcus (1969, p. 7) upon the crop contents of *Retusa sosa* Marcus and Mareus. In the present case, however, the gizzard contents all showed solution effects. Several *Ammonium salsum* were very soft suggesting that the cementing material between the sand grains had been removed, although they retained their normal shape. One *S. fragilis* had had the calcareous shell almost entirely dissolved but again had retained its normal shape. No separate sand grains were found in the intestines as would be

expected from the crushing of arenaceous foraminifera. This indicates that the food is obtained by dissolving of the foraminiferal tests and molluscan shells and slow ingestion of the viscerous masses. Although the gastral plates may act as a sieve as suggested by Mareus and Marcus (1969, p. 7) we prefer to consider that they act in the nature of a vice, holding the food firmly in place as the digestive processes take place. In this respect *R. chrysoma* differs from *Relichna* as Rudman (1971) found evidence for crushing of foraminiferal tests by the gastral plates in *Relichna murchisoni* (Suter, 1913).

Of the four species of opisthobranch present in the biotope only *R. chrysoma* had foraminifera or molluscs in the gizzard.

#### Foraminiferal Reference List

The foraminifera identified are arranged in alphabetical order giving original reference and several more recent references concerned with the Australian region.

*Ammonia* sp. One small specimen is referred to this genus.

*Ammonia aoteanus* (Finlay).

*Strebulus aoteanus* Finlay 1940, *Trans. R. Soc. N.Z.* 69 (4): 461.

*Ammonia aoteanus* (Finlay). Hedley, Hurdle and Burdett, 1967, *N.Z. Dep. sci. industr. Res. Bull.* 180: 47, pl. 11, fig. 4, figs. 56-60.
