## CORALLIMORPHARIA, ACTINIARIA AND ZOANTHIDEA

#### By Charles E. Cutress

Department of Marine Sciences, University of Puerto Rico, Mayaguez

#### **Abstract**

The collection of sea anemones from Port Phillip, Victoria, consists of 15 species, including one corallimorpharian, 12 actiniarians and two zoanthideans. Three are described as new species: *Isophellia stela* (Actiniaria: Isophellidae), *Parazoanthus lividum* (Zoanthidea: Parazoanthidae), and *Epizoanthus sabulosum* (Zoanthidae: Epizoanthidae). Ten species constitute new records for Port Phillip Bay.

#### Introduction

The collection of sea anemones resulting from the Port Phillip Bay Survey apparently is by far the largest and richest ever to come from the area. Represented in the collection are one corallimorpharian, 12 actiniarians (one new species), and two zoanthideans (both new species).

Five species of Actiniaria and one corallimorpharian had previously been reported from Port Phillip Bay. Haddon and Duerden (1896) described Actiniodes spenceri, Sagartia carlgreni, Mitactis australiae, Mitactis similis and Corynactis autralis. The first is now recognized as an Actiniogeton, the last retains Haddon and Duerden's names, and the other three are probably synonyms of Anthothoë albocincta. Duerden (1895) vaguely refers to Cystiactis tuberculosa (now Phlyctenactis) from Port Phillip. Since two of these species, Corynactis australis and Phlyctenactis tuberculosa, are included in the collection under consideration, there are then 16 species known from Port Phillip Bay. For an area the size of Port Phillip, this is an average sea anemone fauna.

Of the 15 species in the 1957-1963 survey collection, the three new species plus *Epiactis australiensis*, *Phlyctenanthus australis* and *Isanemonia australis* are known only from southern Australia. Six other species had previously been reported from southern Australia:

Contribution, Department of Marine Sciences, University of Puerto Rico, Mayaguez, P.R. 00708.

Corynactis australis, Actinia tenebrosa, Oulactis muscosa, Anthopleura aureoradiata, Phlyctenactis tuberculosa, and Anthothoë albocincta. Three species, Epiactis thomsoni, Bunodactis rubrofusca and Cricophorus nutrix, were previously known only from New Zealand and, in addition to the three new species, represent new records for southern Australia (Port Phillip Bay). On the basis of the present analysis, it is apparent that the Port Phillip Bay sea anemone fauna is for the greater part related to that of New Zealand (nine species) and to a lesser extent possibly endemic (seven species). No species that might be considered subtropical appeared in the collection.

Three papers by Carlgren (1950a, 1950b, 1954), dealing with southern Australian anemones, give good accounts of several of the species included in this report. I have, therefore, simply listed these species along with references and collection data, adding comments in only a few instances.

Holotypes of the three new species described in this paper are deposited in the National Museum of Victoria.

I am indebted to Mrs Hope Macpherson Black of the National Museum of Victoria for providing the specimens and data upon which this report is based, to Mr David A. West, Department of Marine Sciences, University of Pucrto Rico, Mayaguez, for the photographs, and my wife, Bertha, for lending a hand, as always where needed.

# Description of Species Order Corallimorpharia

# Family Corallimorphidae Corynactis australis Haddon and Duerden

Corynactis australis Haddon and Duerden, 1896; 151, Pl. 7, fig. 6-10, Pl. 8, fig. 9-10; Carlgren, 1949: 14; Carlgren, 1950b: 131.

Survey areas 10 (12) 2, 12 (112) 1, 19 (304) 1.

# Order Actiniaria Family Actinidae Actinia tenebrosa Farquhar

Actinia tenebrosa Farquhar, 1898: 535; Stuckey, 1909c: 375, 380, Fig. 5, Pl. 23, fig. 1-2; Stuckey and Walton, 1910: 541; Stephenson, 1922: 266; Carlgren, 1924: 196, Fig. 14; Carlgren, 1949: 50; Carlgren, 1950a: 2; Carlgren, 1950b: 132; Parry, 1951: 87, 100; Carlgren, 1954: 571.

Survey areas 58 (79) 20, 59 (Quarantine Jetty, intertidal) 7, 59 (36) 17.

#### Oulactis muscosa (Drayton in Dana)

Metridium unuscosum Drayton in Dana, 1846: 153; 1849 (atlas): 3, Pl. 5, fig. 42, 43; Dana, 1859: 12.

Oulactis utuscosa, Milne Edwards and Haime, 1851: 12; Milne Edwards, 1857: 292; Andres, 1883: 311; Carlgren, 1949: 52; Carlgren, 1950a: 3; Carlgren, 1950b: 134, Fig. 2, Pl. 2; Parry, 1951: 87, 102.

Oulactis plicatus Hutton, 1879: 311; Farquhar, 1898: 527.

Cradactis plicatus, Stuckey, 1909e: 376, 392, Pl. 25, fig. 1-2; Stephenson, 1922: 284.

Survey areas A-5 (58) 1, 5 (Williamstown, intertidal) 3, 9 (84) 17, 24 (122) 2, 27 (Point Wilson, intertidal) 1, 42 (38) 1, 63 (Safety Beach, intertidal) 11, 69 (Rosebud, intertidal) 1.

The three largest specimens from area 63, having lengths of 25 mm and diameters of 20 and 15 mm, all have 96 tentacles and 48 pairs of mesenteries of which all were fertile except the directives and youngest eyele. The entoderm of the tentacles, oral disc and upper column is coloured dark sepia from abundant zooxanthellae. The marginal sphineter is weak and diffuse in all three area 63 specimens but in others from Anglesea the sphineter varied from weak, diffuse, to moderately strong, circumseript. Nematocysts of the marginal spherules of the area 63 specimens were holotrichs  $40-50 \times 4-5 \mu$  and spirocysts,  $28 \times 2 \mu$ .

## Anthopleura aureoradiata (Stuckey)

Bunodes aureoradiata Stuckey, 1909a: 368, Pl. 17; Stuckey, 1909c; 376, 394.

Anthopleura aureoradiata, Carlgren, 1924; 208, Fig. 17; Carlgren, 1949; 54; Carlgren, 1950a; 3; Parry, 1951; 88, 104, Figs. 5-6; Carlgren, 1954;

574, Fig. 3.

Survey areas 9 (84) 11, 27 (Point Wilson, intertidal) 20, 69 (Rosebud, intertidal) 13, label macerated (Vietoria 21 Feb. 62) 4.

The anemones from the lot with the macerated label were attached to the bivalve *Katelysia scalarina*. The largest specimen measured 20 mm in length by 8 mm in diameter and contained several 12 to 14-tentacled young among the mesenteries.

#### Epiactis australiensis Carlgren

Epiactis australiensis Carlgren, 1950a; 5, Fig. 2; Carlgren, 1954: 576.

Survey area 55 (35) 2.

#### Epiactis thomsoni (Coughtrey)

Actinia thomsoni Coughtrey, 1874: 280.

? Actinia thomsoni, Hutton, 1879: 313; Farquhar, 1898: 527.

Leiotealia thompsoni, Stuckey, 1909b: 370, Pl. 18, fig. 1-2, Pl. 19, fig. 1-3; Stuckey, 1909c: 376, 395. Epiactis thompsoni, Stephenson, 1922: 274; Carlgren, 1924: 221, Fig. 25; Parry, 1951: 88, 111.

Epiactis thomsoni, Carlgren, 1949: 58.

Survey areas 13 (93) 3, 18 (61) 3, 23 (3) 7, 27 (41) 1, 42 (38) 1, 55 (Mornington, intertidal) 1, 59 (23) 1.

The specimens from Port Phillip agree closely with the descriptions given by Carlgren (1924) and Parry (1951). A large specimen from area 55 contained a number of 12-tentaeled young in the marginal stoma.

## Phlyctenactis tuberculosa (Quoy and Gaimard)

Actinia tuberculosa Quoy and Gaimard, 1883: 159, Pl. 11, fig. 3-6.

Cereus tuberculosus, Milne-Edwards, 1857: 268.

Cystiactis tuberculosa, Haddon and Duerden, 1896: 156, Pl. 7, fig. 11, Pl. 9, fig. 1-3; Duerden, 1895: 213; Lager, 1911: 217; Stephenson, 1922: 286.

Phlyctenactis retifera Stuckey, 1909s: 376, 396, Pl. 26, fig. 1-2.

Phlyctenactis morrisonii Stuckey, 1909c: 396, Pl. 27, fig. 1.

Phlyctenactis tuberculosa, Carlgren, 1945: 13; Cargren, 1949: 61; Carlgren, 1950a: 136, Fig. 6; Carlgren, 1954: 578, Fig. 8; Parry, 1951: 88, 113.

Survey areas 30 (280) 1, 47 (29) 1, 59 (25) 1.

#### Phlyctenanthus australis Carlgren

Phlyctenathus australis Carlgren, 1950b: 135, Fig. 3-5, Pl. 1; (nomen nudum) Carlgren, 1949: 61. Survey area 58 (90) 1.

#### Bunodactis rubrofusca Carlgren

Bunodactis, rubro-fusca Carlgren, 1924: 204, Fig. 15-16; Carlgren, 1949: 65.
Bunodactis rubrofusca, Parry, 1951: 88, 115.

Survey area 42 (38) 3.

## Isanemonia australis Carlgren

Pl. 9, fig. 2 Isanemonia australis Carlgren, 1950a: 7, Fig. 3; Carlgren, 1954: 575, Fig. 4-5.

Survey areas 55 (Southside Schnapper Point, intertidal) 4, 58 (Point Lonsdale, intertidal) 2, 59 (80) 2.

The Port Phillip Bay specimens seem to differ in several ways from the speeimens described by Carlgren (1950a, 1954). It is chiefly these differences that are described here. As the species has never been illustrated, a photograph of the best preserved specimen is included (Pl. 9, fig. 2). The three largest specimens examined had column heights, oral dise diameters and pedal dise diameters, respectively and in centimeters, of 3, 3, 2; 3, 3.5, 2.5; 5, 5, 6. The tentacles numbered 140 ( $\pm$ 5), and the longest measured 3 em. This is certainly not consistent with Carlgren's diagnosis of the genus: 'tentaeles not very numerous, of moderate length'. Although these specimens were as large or larger than Carlgren's and well-expanded, I eould not deteet marginal pseudospherules which the species is said to have. The entodermal sphincter musele of the sectioned specimen is somewhat stronger than that depicted by Carlgren (1950a, Fig. 3a) but is comparable to that illustrated later by Carlgren (1954, Fig. 4). The sphincter extends for about 3 mm along the wall of the deep fosse and eonsists of 120 or more mesogloeal pleats (300  $\mu$  high) many of which are branched. The mesogloea is fibrous and cellular throughout. The sectioned specimen is a ripe male. The numbers of mesenteries are exactly the same at the margin and base. Nematocysts examined are: spirocysts of tentacles,  $30 \times 2 \mu$ ; holotriehs of limbus, 25-26  $\times 5 \mu$ ; microbasic b-mastigophores of limbus,  $21 \times$  $2.5 \mu$ ; of filaments,  $35 \times 5 \mu$ ; of actinopharynx, 28-30  $\times$  4·5  $\mu$ ; of tentacles, 28-30  $\times$  3  $\mu$ ; microbasic p-mastigophores of filaments, 20  $\times$  5  $\mu$ ; of actinopharynx, 24-25  $\times$  5-6  $\mu$ .

#### Family Isophellidae

# **Isophellia stela** n.sp. Fig. 1, Pl. 9, fig. 1

MATERIAL: Survey areas 7 (123) 2, 33 (177) 2.

HOLOTYPE: Nat. Mus. Vict. G1547. Three Paratypes G1548.

Type Locality: Off Middle Brighton.

Description: The specimens from area 33 are both strongly contracted, and in this state both have total lengths and greatest diameters of  $10 \times 5$  mm. They are attached to tough, white fibrous material, probably a polychaete tube. The specimens from area 7 are both well expanded and have total lengths of 20 mm and greatest diameters of 7 mm.

The column is divisible into a short, distinct, clean, thin-walled scapulus and a thick-walled scapus bearing prominent tenaculi in its distal half. The contracted specimens have sand grains adhering to the tenaculi while the expanded specimens are free of sand. The columns of all specimens are constricted just above the pedal discs, this being more evident in the contracted specimens. Cinclides were not evident.

The tentacles are thin, evenly-tapered and acute. The inner are up to 6 mm in length and are twice or more the length of the outer. There are  $80 \ (\pm 2)$  tentacles on each of the two specimens. Considering the number of mesenteries, it is likely that the definitive number of tentacles would be 96.

Ectoderm of column 30 to 75  $\mu$  high, with a few gland cells containing neutrophilic granules but lacking mucous cells. A surface cuticle seems to be lacking even on the tenaculi.

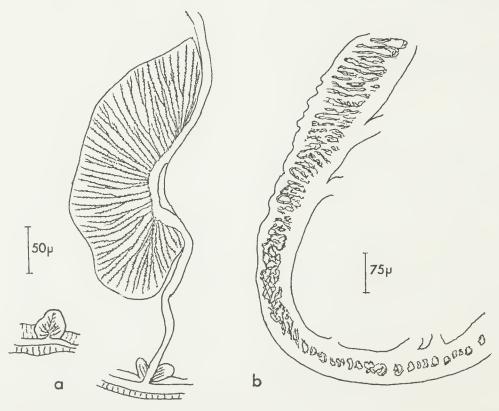

Fig. 1—Isophellia stela n. sp., a, second cycle macrocneme and a microcneme; b, marginal sphincter (only mesogloea shown).

Entoderm of the column 12 to 25  $\mu$  high, with a few gland cells and no zooxanthellae. Circular muscle layer of column folded into pleats 25  $\mu$  high near margin and diminishing to 6 to 8  $\mu$  at mid column. Radial muscles of oral disc and longitudinal muscles of tentacles ectodermal.

Mesogloca fibrous and cellular throughout, that of the mid column 12 to 40  $\mu$  thick. Marginal sphincter in the mesogloca strong, stratified near the margin and gradually becoming alveolar down the column. The sphincter, in section, is about 700  $\mu$  long by 75  $\mu$  at its greatest width. In its upper portion it occupies most of the width of the mesogloca but in its lower portion, only about one third.

Mesenteries are distinctly divisible into macrocnemes and microcnemes. Twenty-four pairs of mesenteries extend from pedal disc to oral disc. Of these the first cycle (two pairs directives) and most of the second are macrocnemes and are perfect and fertile. The retractor muscles of the second cyclc mesenteries are slightly weaker than those of the first cyclc. In addition, one member of each pair of second cycle mestenteries is noticeably weaker than the other and is always the same member with respect to the directive axis. In the sectioned specimens one member of a second cycle pair is an imperfect, very weak macroeneme while a member of another pair is a microcneme. The retractor muscles of the macrocnemes are very strong and of the restricted type. The stronger are made up of 40 or more high pleats of which many are branched. The parietal muscles of both macro- and microcnemes are of similar shape and strength. They are strong and are made up of six to 10 mostly unbranched pleats. The basilar muscles are weak but distinct. The micronemes, throughout most of the column length, consist of little more than parietal muscle. Twelve pairs, or a few more, run the length of the column, lack filaments and are sterile. In the region of the short scapulus there occurs part of an additional cycle of very weak micronemes (16 pairs in the sectioned specimcn). This accounts for the species having more tentacles than mesenteries at the pedal disc.

The acontia are sparse and short. In cross section they are circular rather than triangular, about 150  $\mu$  in diameter, and the nematocyst tract occupies about one third of the circumference. The specimens sectioned are ripe males.

The actinopharynx is longitudinally corrugated. Its ectoderm contains very numerous, small, dark-staining nuclei and pale-staining nucous cells. There are two prominent siphonoglyphs.

Cnidom: Spirocysts of tentacles 15-18  $\times$  2·5  $\mu$ , numerous. Microbasic b-mastigophores of tentacles 18-20  $\times$  2-2·5  $\mu$ , common; of column, 18  $\times$  2·5  $\mu$ , few; of actinopharynx, 30  $\times$  3  $\mu$ , numerous; of acontia. 28-32  $\times$  3-4  $\mu$ , numerous. Microbasic p-mastigophores of tentacles 17  $\times$  3  $\mu$ , few; of column, 13  $\times$  3  $\mu$ , few; of actinopharynx, 16  $\times$  4  $\mu$ , common; of filaments, 11-14  $\times$  4  $\mu$ , few; of acontia, 32  $\times$  4  $\mu$ , numerous.

REMARKS: The specimens here identified as Isophellia stela resemble very closely I. sabulosa Carlgren (1900: 52, Pl. 1, fig. 9) from Zanzibar. An obvious difference, but one that I think may reflect environment, is the complete investment of the I. sabulosa scapus with sand while only the upper half of the scapus in I. stela is covered. A discrepancy of more importance is the apparent lack of cinclides in the Port Phillip Bay specimens. Cinclides, however, are frequently difficult to observe in many of the Isophellidac, especially so in preserved specimens. Carlgren (1928) added to the description of I. sabulosa. Here his text figures 68 of the sphincter, 71 of the mesentery and 72 of the parietal muscle are virtually identical to depictions of those same structures in I. stela. On the other hand, all types of nematocysts from I. stela are somewhat larger than those of I. algoensis Carlgren (1928). Carlgren separated algoensis from sabulosa largely on the basis of the larger nematocysts in the former species.

Primarily on the basis of the larger nematocysts in *I. stela* but also with consideration of the more tropical range of *I. sabulosa*, I consider the Port Phillip Bay specimens to represent a new species.

#### Family SAGARTHDAE Anthothoe albocincta (Hutton)

Gregoria albocincta Hutton, 1879: 312 Sagartia albocincta, Stuckey, 1909b: 372, Pl. 20, fig. 2-3; Stuckey, 1909c: 376, 382; Stuckey and Walton, 1910: 541.

? Actinothoe albocincta, Carlgren, 1949: 103. Anthothoe albocincta, Carlgren, 1950a: 10; Carlgren, 1950b: 142, Pl. 3, fig. 1; Parry, 1951: 89; Parry, 1952: 129; Carlgren, 1954: 584.

Survey areas 10 (103) 7, 25 (129) 7, 29 (107) 5, 43 (303) 3, 59 (80) 9, 59 (24) 1, 59 (25) 2, 61 (37) 44.

REMARKS: The Port Phillip Bay specimens agree well in anatomical features with specimens from New Zealand. However, the nematocysts, especially of the acontia, arc somewhat longer in Port Phillip specimens. In New Zealand specimens they are 50-65  $\times$  7  $\mu$  microbasic p-mastigophores and 20-25  $\times$  2  $\mu$  microbasic b-mastigophores while in those from Port Phillip these nematocysts are  $70-90 \times 6-7 \mu$ and 30  $\times$  2  $\mu$ , respectively. The p-mastigophores appear to have detachable 'darts' on the end of the shaft. This discrepancy in nematocyst sizes is also noted by Carlgren (1950a). I tend to agree with him that the observed differences, in this case, are not especially meaningful.

## Family Hormathidae **Cricophorus nutrix** (Stuckey)

Sagartia nutrix Stuckey, 1909c: 376, 382, Fig. 6, Pl. 21, fig. 1-2.

Cricophorus nutrix, Carlgren, 1924: 252, Fig. 44-53; Carlgren, 1949: 96; Carlgren, 1950a: 8; Parry, 1951: 89; Parry, 1952: 125; Carlgren, 1954:

Survey area 59 (36) 1, 69 (Rosebud, intertidal), 8.

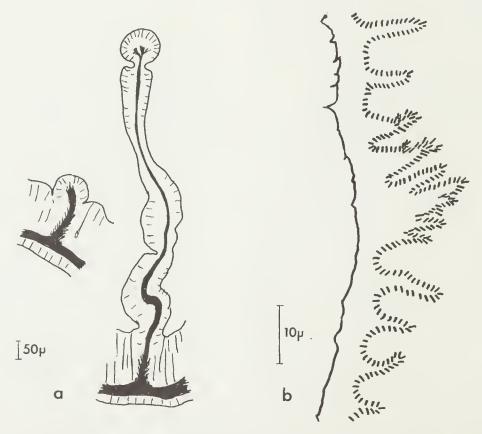

Fig 2—Parazoanthus lividum n. sp., a, microcneme and macrocneme; b, marginal sphincter (only mesogloea shown).

Order Zoanthidea
Family Parazoanthidae
Parazoanthus lividum n.sp.

Fig. 2, Pl. 9, fig. 4

MATERIAL: Survey area 6 (off Williamstown 29/6/58) 2 specimens.

HOLOTYPE: Nat. Mus. Vict. G1549.

PARATYPE: G1550.

TYPE LOCALITY: Off Williamstown, Vict.

DESCRIPTION: The zoanthids in both lots are on the sponge Spirasterella sp. According to Dr Patricia Berquist, the zoanthid is dull bluishgrey and the sponge, yellow ochre. In preservative the zoanthids of one lot are yellow ochre while in the other they are a pale violet-brown. The pieces of sponge are rather well covered by several colonics of zoanthids which consist of two to more than 100 polyps per colony. For the most part the coenenchyme, flattened, band-like and two to 4 polyps wide, meanders in the depressions between nodules on the sponge surface. However, at the distal end of the sponge the coenenchyme is sheet-like and almost completely caps the rounded end of the sponge. In the proximal region of the sponge the colonies are small and scparate. The largest opened polyp measures 2 mm in diameter and extends 1 mm above the surface of the coenenchyme. Some of the closed polyps are flush with the surface of the coenenchyme while most appear as hemispheres. The polyps are close together, many with their margins touching. Small polyps are interspersed randomly among large ones. Incrustation consists of fine, uniform-sized grains of quartz and calcareous sand plus a few sponge spicules. It is moderately dense on the polyps, sparse in the middle of the coenenchyme band, and virtually absent along the edges of cocnenchyme. The ridges of the scapulus number to 16 and are distinct in semi-open or open polyps. The tentacles number to 29.

Marginal sphincter is entodermal, occupying the entire length of the scapulus (about 120  $\mu$  long). It consists of 10 to 12 pleats of which the highest is about 20  $\mu$ . The mesogloea in this area is about 6  $\mu$  thick.

Mesenteries number to 29 in large specimens with 16 being macroenemes and 13, micro-

nemes. The retractor muscles of macrocnemes are very weak and consist of a thin sheath of fibres without underlying mesogloeal pleating. The filaments are of typical shape, are ciliated, contain numerous nematocysts as well as acidobasophilic gland cells. The parietal portions of the macrocnemes, with respect to the appearance of the mesogloca and musele fibres, are very similar to microenemes. Here the mesogloca is thick (25  $\mu$ ) and the muscle fibres arc borne on low mesogloeal pleats. The microenemes extend out from the column mesogloea a distance equal to or slightly greater than the thickness of the column entoderm (about 125  $\mu$ ). All specimens sectioned laeked discernible gonads.

The actinopharynx is longitudinally corrugated. The siphonoglyph is shallow but distinct. The hyposulcus is slightly shorter and indistinct.

The mesogloca is acellular and in the column contains incrustation and lacunae with entodermal cells. A distinct encircling sinus was not apparent but some of the cords of entodermal cells could have been part of such a sinus.

The ectoderm of the column is disrupted by the incrustation. Intact portions (about 30  $\mu$  thick) contain numerous holotrichs and also acido- and basophilic gland cells.

The entoderm contains zooxanthellae in abundance as well as acido- and basophilic gland cells.

Cnidom: Spirocysts of tentacles, 15-20  $\times$  3  $\mu$ , numerous. Microbasic b-mastigophores of tentacles, 16-17  $\times$  2-2·5  $\mu$ , common; of actinopharynx, 18-21  $\times$  2·5-3  $\mu$ , common. Microbasic p-mastigophores of tentacles, 15  $\times$  3-4  $\mu$ , common; of filament, 15-19  $\times$  4  $\mu$ , common. Holotrichs of filaments, 22-25  $\times$  10-12  $\mu$ , few; of column ectoderm, 20-25  $\times$  10  $\mu$ , numerous.

REMARKS: Only Parazoanthus capensis Duerden (1907: 180, Pl. 11) from South Africa seems sufficiently close to P. lividum to warrant close comparison. Carlgren (1938: 95, Fig. 48, Pl. 1, fig. 4) has given further details of this species. First, P. capensis occurs on a different species of sponge, is pale yellow in-

stead of bluish-grey, and the colonies seem never to have as many polyps as the majority of colonies of P. lividum. The polyps of P. capensi are twice the size of those of P. lividum and have 14 scapular ridges instead of 16. The nematocysts of P. capensis are in general 2-4  $\mu$  longer than in P. lividum. In view of these discrepancies and the geographic separation of the two species, I consider the Port Phillip Bay specimens a new species.

Family EPIZOANTHIDAE **Epizoanthus sabulosum** n.sp.

Fig. 3, Pl. 9, fig. 3
Survey area 58 (293) 1 colony.
HOLOTYPE: Nat. Mus. Vict. G1551.
Type Locality: Point Lonsdale, Vict.

DESCRIPTION: The single lot of zoanthids from area 58 were on a delicate, branching sponge about 8 cm high. The several colonies on

the sponge take the form of tight clusters of up to 6 polyps. Interspersed among these are single polyps. There is a total of about 100 polyps on the sponge. None of the polyps is expanded. The largest of the least contracted polyps is 4 m high and a greatest diameter of 3 mm. The coenenchyme is flattened and scarcely exceeds the circumference of the polyp's base. Both the polyps and coenenchyme are densely incrusted with quartz sand grains. The scapular ridges number to 15, are prominent and are heavily incrusted. Tentacles number to 30 in large polyps.

Marginal sphincter muscle in the mesogloea, alveolar, the 16 to 18 alveoli situated about mid mesogloea. The sphincter is moderately

strong, about 200  $\mu$  long in section.

The mesenteries number to 30 of which 15 are macrocnemes and 15 are microcnemes. The macrocnemes bear filaments and are fertile. The specimens sectioned are female.

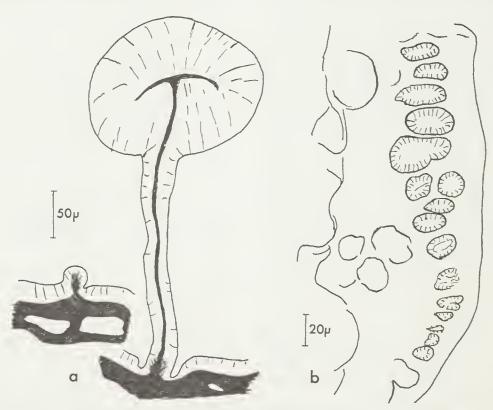

Fig. 3—Epizoanthus sabulosum n. sp., a, microeneme and macroeneme; b, marginal sphincter (only mesogloea shown).

The musculature of the macroenemes extremely weak and consists of only a thin layer of fibres against the mesoglocal lamella. The mesogloca in the parietal part of the mesenteries is about three times as thick as the rest of the mesentery lamella and is pleated against the parietal muscle. The microenemes are similar in shape and size to the thickened parietal portions of the macroenemes. The filaments on the macroenemes are of typical shape in sections but are exceptionally thick.

The actinopharyax is longitudinally corrugated. A distinct siphonoglyph and an indistinct hyposuleus are present.

The mesogloca of the column is thick and contains much incrustration as well as isolated nests of ectodermal cells and acido- and basophilic gland cells.

The ectoderm of the column is greatly interrupted because of the dense incrusation but where present is up to 25  $\mu$  thick.

The entoderm contains numerous zooxanthellae, a feature unsual for members of this genus.

Cuidom: Spirocysts of tentacles 15-22 ×  $2.5-3 \mu$ , numerons, Microbasic b-matigophores of tentacles 16-20  $\times$  2  $\mu$ , few; of actinopharynx,  $16 \times 2.5 \,\mu$ , few. Microbasic p-mastigophores of lilaments 16  $\times$  4  $\mu$ , common. Holotrichs of column 15-20  $\times$  8-10  $\mu$ , few.

REMARKS: Of the 17 species of Epizoanthus known from the Pacific and Indian Oceans, nine species are free-living, four form carcinoecea, two are symbionts of gastropods, and two are symbionts of Hyalonema. Many of these species can be eliminated from consideration solely on the basis of their geographical and/or bathymetrical range or their growth form. I have not exhaustively compared all other species but I cannot find in my collection or in the literature any species of Epizoanthus that is similar enough to the Port Phillip species to warrant a detailed comparison The Port Phillip species seems to be unique from the standpoint of the type of sponge on which it is found, its occurrence in shallow water, its size, number of septa, and in its possession of zooxanthellae.
